Environment variables

Posted by blpagno - 2009/11/06 17:25

Hi

is there a way to use the variables like {rel_site_dir} in a module or component of a slave site?

I'm using the Random Picture module and I want to separate the pictures of each slave site, but I don't want to do that manually!

Or... another option would be coding... is there a variable in code that I can get the path to the current slave site?

Thanks in advance

Bruno

You have a define that is set each time you have a slave site that is active.

```
if ( defined( 'MULTISITES_ID' ) ) {
// this is the slave site identifier
}
else {
// this is the master website
}
```

So you can use the "MULTISTIES_ID" to compute a name or a file, picture or whatever.
This is the internal define that is used by JMS to suffix some configuration file to make it unique.
