Feature Request
Posted by mismarketing - 2010/10/01 11:21

I would like a feature that in the site manager instead of having to edit and save each slave site when i change the master, i can have a check box and apply to all.

currently there is a radial button next to the slaves and edit on the top i would like to see a button to update all somehow.

Thanks

Which kind of "common" slave site definition you would like to have applied for all the slave sites ?

Do you want for example to just change the DB connection for all the slave site in one shot ?

Which kind of changes you are doing in the master that you would like to see applied in the slave site definition ?

---

changes to components, modules, plug-ins and shared articles would be great

Edwin I have another feature request. This actually could be an add-on I would pay for immediately.

I have a component called "content enhancer" it allows for article variables, and global replacements.

What I would like it a multisite content variables component. When i can build a list of variables that I can place in data in my master. Then when i login to the slave i can go to the component and assign the value for the replacement in the slaves site content.

I would want this to work in many areas of content. Articles, MetaData, Titles, even something like

template mods. for google analytics or a hard link to my mobile site m.slave.com can be a global variable replacement.

so if you gave me a component that let me put in master value then place the {var} anywhere in the master i want then replace the slave value in the component it will dynamically change the content value.

Example. I make master site Mailing Address as my var. It makes me a {master_add_var} i place anywhere i need it, articles, meta, even templates. then in the slave i login to the component and replace master address text value to: 123 street

I know id need to make one for city, state, phone anything i want. but then i could edit values on my slaves all in one window quickly to deploy slave sites.

Let me know. I would pay for this.

This extension already exists and is our free Search/Replace plugin
http://www.jms2win.com/free-download/doc_download/13-search--replace-utility

It does not work exactly like you explained but you can create Search/Replace list in a file on the disk and it is also possible to have specific list for each slave sites.
So you could configure the plugin a website that you replicate and always use parameters that are defined in a file on the disk.
So the user interface for the Search/Replace is not a Joomla component but a file (or several files) on the disk that you can manage with your FTP tool.

As this is a system plugin it works on all the elements of the page (modules, component, meta, ...)

i have another feature i think i need, unless it exists.

this week i updated rsForm Pro. and all my slaves stopped working. i had to manually install each slave to make the new version work.

this is sort of like my previous post. what cant i push a new component, module, or plugin to all sites...and at once?

i knwo i can open then save the slave in the multi manager but it didnt work in this instance.

it would be really nice for this to be easier.

Thanks

When you use the JMS tools, you can click in the checkbox to propagate to all the children.

So if you have adopted an architecture that allow propagate a same action to all the children then you can already do it.

See also the tutorial video 0.b slide 24 that show for example a slave1 and all the children.
http://www.jms2win.com/tutorial#jms12x-0b
