Setting up TEMPLATE, Need help

Posted by Jweber72 - 2010/10/10 04:00

Ok, I just bought the newest version and I'm looking for some help getting my template setup.

I want to be able to have the master site duplicated when I create a subsite. In the Deployment folder I'm wondering how to setup the field.

It is my understanding you can have variables and I'm thinking "{multisites}/{site_id}" is how to fill this in? Is this correct?

Also, I'm not sure how the database name is created? I have {site_id} in the DB Prefix fields so does that mean the database name will be the Site ID? Also is the site ID the word or the ID number of the slave site?

To replicate the master, get inspired of tutorial video 13 or 16 or CP-05 that show some sample of JMS templates menu.

You have to select the "template site" = as this is the wesbite that you want to replicate.
When using the prefix = {site_id}_ that mean that you create the new website with this table prefix resolved with the Site ID that you will enter in the JMS Mnanage menu.
If you let the "New DB " parameter empty, this mean that you create the new website in the same DB (here in the sample in the same DB than the master).

The deployed directory must be in line with the domain name that you have specified and its location on the disk.
So if you have setup the domainA.com located in document root = /multisites/domainA
then your deployed directory is {multisites}/{site_id} when Site ID = domainA.

This is also the case when domain = {site_url}/multisites/{site_id}.
In this case the location on the disk for the deployed direcotry = {site_dir} that is the equivalent of {multisites}/{site_id}
