Issues updating plugins/mods/components

Posted by kremedia - 2011/07/15 15:23

Hi

When I go to 'tools' and select a website that is not in my master db, I can uninstall and install components/modules/plugins fine. However, when I try to do it on the master database and propegate to children and also overwrite the files, I get the following error:

Fatal error: Call to a member function getPrefix() on a non-object in /...../administrator/components/com_multisites/classes/multisitesdb.php on line 661

I tried reproducing it without success.

Normally the Tool menu should use with the slave site and not to propage extension when selecting the master.
Anyway, I am interested to know more on how to reproduce that.

I have a master website with slave site that is a replication of the master.
When I have installed an extension in the master, I have after that use the "tool" menu and click on the master where I have selected the extension to propagate.
In my case, I didn't received any error message.

So, would you please give a detailled scenarion that show how to reproduce it.

Would you also provide information on the environment.
Which joomla version ?
Which Jms Multisite version ?
Which extension you try to propagate to the children ?
