Multisite and apache configuration
Posted by cyberconseil - 2009/08/24 18:14

_____

Hello,

I create a slave site for this URL

http://blog.cvo-cyberconseil.com

I change my apache configuration in order to create a new virtualhost

ServerName blog.cvo-cyberconseil.com
DocumentRoot /home/joomla/multisite/multisites/blogcvo

It seems to work when I connected to the site. But when I connect to the administrtion site
URL : http://blog.cvo-cyberconseil.com/administrator

All the change ar written to the wrong database (the master). I'm usin a single database configutation
(master & slave in the same Database) The master prefix is multi and the slave prefix is blogcvo. All the
table for blogcvo exists.

Whats wrong with my configuration ? Why the administration site use the master database and not the
slave

Thanks for your help and excuse me for my poor english.

Philippe

_____

First you can check the apaches configuration with the "hello world" procedure.
The idea is to install the hello.txt and hello.php file in the directory
/home/joomla/multisite/multisites/blogcvo

If you see this file correctly when using the blog.cvo-cyberconseil.com domain name, this mean that the
apaches virtualhost is probably well configured.

The second point to check is to verify you have spelled the domain name in the slave site definition that
you have enter in JMS.
When JMS does not find the domain in the list of website, it automatically display the master website by
default.

You also have to check in JMS that you have deployed the slave site into the directory
/home/joomla/multisite/multisites/blogcvo

ps: I also speak french is that may help you.
